**Abstract:** Plasma degradation is one of the most effective methods for the abatement of greenhouse gas sulfur hexafluoride (SF<sub>6</sub>). To evaluate the potential of MgO as a catalyst in plasma degradation, we investigate the catalytic properties of MgO on SF<sub>6</sub> adsorption and activation by density functional theory (DFT) where the O-defective and hydroxylated surfaces are considered as two typical plasma-generated surfaces. Our results show that perfect MgO (001) and (111) surfaces cannot interact with SF<sub>6</sub> and only physical adsorption happens. In case of O-defective MgO surfaces, the O vacancy is the most stable adsorption site. SF<sub>6</sub> undergoes a decomposition to SF<sub>5</sub> and F over the O-defective MgO (001) surface and undergoes an elongation of the bottom S-F bond over the O-defective (111) surface. Besides, SF<sub>6</sub> shows a physically adsorption at the stepsite of the MgO (001) surface, accompanied by small changes in its bond angle and length. Furthermore, SF<sub>6</sub> is found to be physically and chemically adsorbed over 0.5 and 1.0 ML (monolayer) H-covered O-terminated MgO (111) surfaces, respectively. The SF<sub>6</sub> molecule undergoes a self-decomposition on the 1.0 ML hydroxylated surface via a surface bonding process. This study shows that defective and hydroxylated MgO surfaces have the surface capacities for SF<sub>6</sub> activation, which shows that MgO has potential as packing material in SF<sub>6</sub> waste treatment in packed-bed plasmas.

## 1 Introduction

In recent decades, SF<sub>6</sub> has been widely used in the power industry as a dielectric gas, due to its excellent properties on insulation and arc extinction [1]. However, SF<sub>6</sub> is a greenhouse gas and is listed as one of the restricted emission gases in the Kyoto protocol [2]. The global warming potential of SF<sub>6</sub> is 23500 times that of CO<sub>2</sub> [3]. Therefore, its increasing use and emission cause great threats to the atmospheric environment.

Since the end of last century, great efforts have been made on SF<sub>6</sub> abatement. The most used method is thermal degradation, where SF<sub>6</sub> is decomposed and reacts with CaO or Ca(OH)<sub>2</sub> in a 1100° C furnace[1]. However, the maintenance of high temperature and the overload of alkaline solids leads to high energy consumption. By adding metallic phosphate or metallic oxide, the degradation temperature of SF<sub>6</sub> can be lowered to 600~900 K, gaining a better energy efficiency, but the degradation rate is limited [4, 5]. Besides, researchers found that non-thermal plasma (NTP) holds promise for SF<sub>6</sub> abatement, by means of dielectric barrier discharges (DBD), micro-discharges, radio-frequency discharges, and so on [6]. In NTP treatment, the SF<sub>6</sub> molecules can be effectively degraded at atmospheric temperature and pressure, but toxic gas products like SO<sub>2</sub>F<sub>2</sub>, SO<sub>2</sub>, and HF are generated. The addition of metal oxide like Al<sub>2</sub>O<sub>3</sub> in NTP, typically as a packing material in a

so-called packed bed DBD, improves the degradation of SF<sub>6</sub> and regulates its reaction pathway [7, 8]. In 2020, Yael et. al. achieved a sustainable and tunable degradation of SF<sub>6</sub> by a Mg/MgO plasmon-catalytic system, where the S and F elements are fixed as MgF<sub>2</sub> and MgSO<sub>4</sub>, respectively. The reacted Mg products can then be reduced by hydrogen plasma for reuse [9]. Although the degradation rate is limited in the above study, it shows the potential of MgO for SF<sub>6</sub> catalytic degradation. In a plasma-catalytic system, the plasma discharge has significant impact on the packing material surface, thus affecting the surface reactions [10, 11]. For instance, during a thermal or a NTP-based degradation of SF<sub>6</sub>, O<sub>2</sub>, H<sub>2</sub>O and H<sub>2</sub> are often added as reactive gases to promote the degradation and regulate the product distribution [12, 13]. MgO therefore could be affected from the gas environment to form O-terminated surfaces in O-rich conditions and get hydroxylated by H species [14, 15]. To further evaluate the catalytic property of MgO and whether it can be integrated with other technologies, such as thermal catalysis and plasma catalysis (i.e., as packing material in packed bed DBD plasmas), the interaction between SF<sub>6</sub> and MgO should be carefully investigated.

In this work, we carried out a density functional theory (DFT) study on the adsorption and the decomposition of SF<sub>6</sub> over MgO surfaces. The (001) and O-terminated (111) surfaces are selected as the typical MgO surfaces since they have been extensively studied in previous works as the representative catalytic surfaces [16, 17]. The O vacancy, stepsite and H coverage are taken into consideration to better describe the surface conditions that correspond to the actual MgO materials in plasma-catalysis. Charge analysis is carried out to uncover the bonding and the charge transfer processes between the SF<sub>6</sub> molecules and the MgO surfaces. The results reveal that chemical adsorption only happens over special sites, like O vacancies and H-covered surfaces. Our study demonstrates that MgO is a potential catalyst or packing material for SF<sub>6</sub> degradation in NTP abatement.

## 2 Computational details

The DFT calculations are carried out by the CP2K/Quickstep package [18]. The generalized gradient approximation of Perdew-Burke-Ernzerhof functional is applied to describe the exchange-correlation terms [19]. The DFT-D3 method is used for the dispersion correction [20]. The Goedecker-Teter-Hutter (GTH) pseudopotentials are applied to describe the core electrons [21], and the Gaussian and plane wave method (GPW) is applied, with a plane wave cutoff to be 800 Ry [22]. The molecularly optimized double- $\zeta$  polarized basis sets (m-DZVP) are applied for the expansion of the wave functions. Bader analysis is used to describe the charge transfer process [23].

The (001) and O-terminated (111) MgO slab models are built, as shown in Fig. S1. Both slabs have five layers and the bottom two layers are fixed during the calculation. The XY dimensions are 11.91×11.91 Å for both slabs and a vacuum layer of 30 Å is applied to avoid periodic interactions. The O vacancy is made by removing one of the O surface atoms from the (001) and (111) surface, as shown in Fig. S2 [24, 25]. The step site of the MgO (001) slab is made according the Ref. [26], where the atoms in the right part of the surface layer are removed and the edge composed of O atoms is exposed. The O-terminated MgO (111) surfaces with H coverages of 50% or 100% (labelled to be 0.5 and 1.0 ML) are made according to Ref. [27] to simulate the hydration effects of the MgO material, as shown in Fig. S3. During the calculation, the surface dipole correction is applied for the MgO (111) surfaces.

The adsorption energy  $E_{ad}$  of gas molecules on the MgO surface is calculated by Eq (1).

$$E_{ad} = E_{gas+slab} - E_{gas} - E_{slab} \quad (1)$$

Where  $E_{\text{gas}}$  and  $E_{\text{slab}}$  are the energies of gas molecules and of the MgO slabs, respectively, and  $E_{\text{gas+slab}}$  is the total energy of the adsorbed system. A more negative  $E_{\text{ad}}$  corresponds to a more stable adsorption.

### 3 Results and discussion

#### 3.1 SF<sub>6</sub> adsorption on perfect MgO (001) and (111) surfaces

The stable adsorption configurations of SF<sub>6</sub> over perfect MgO (001) and (111) surfaces are calculated, as shown in Fig.1 and Fig.2. For each site, two kinds of initial configurations are considered, one of them is the S-F bond set perpendicular to the surface, and the other is the two bottom F atoms parallel to the surface. The configuration with a more negative  $E_{\text{ad}}$  is considered to be the stable one. The adsorption energies  $E_{\text{ad}}$  and the distance between SF<sub>6</sub> and the slab surface are summarized in Table 1. In Fig.1 and Fig.2, there is no chemical bonding made between the SF<sub>6</sub> molecule and the MgO surfaces. At the same time, the SF<sub>6</sub> molecule structure has no obvious change after the adsorption and this indicates that only physical adsorptions happen. The  $E_{\text{ad}}$  of SF<sub>6</sub> at Mg, O and the hollow sites over the MgO (001) surface are all the same, i.e., -0.21 eV, while SF<sub>6</sub> adsorbing at the hollow site has the smallest adsorption distance of 2.45 Å. By contrast, over the MgO (111) surface, the most stable adsorption shows up at the hollow site, with the highest  $E_{\text{ad}}$  to be -0.23 eV. However, SF<sub>6</sub> adsorbing at the hollow site shows the largest adsorption distance to be 2.71 Å. The smallest adsorption distance shows up at the Mg site, with  $E_{\text{ad}}$  to be only -0.16 eV. These results indicate that the interaction between the SF<sub>6</sub> molecule and the perfect MgO surfaces is very weak and the adsorption process is mainly induced by the Van der Waals forces.

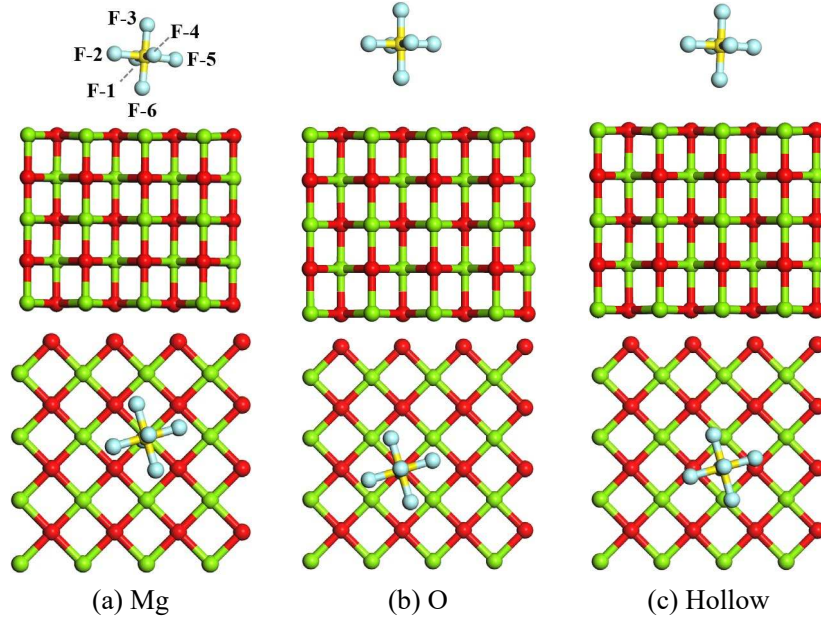

Fig. 1 Adsorption configurations of SF<sub>6</sub> over the perfect MgO (001) surface, in side view (upper panels) and top view (lower panels). Green, red, yellow and blue balls are Mg, O, S and F atoms, respectively.

Table 1 Adsorption energy and distance of SF<sub>6</sub> over perfect MgO (001) and (111) surfaces

Adsorption site	MgO (001)		MgO (111)	
	$E_{\text{ad}}$ (eV)	Adsorption distance <sup>a</sup> (Å)	$E_{\text{ad}}$ (eV)	Adsorption distance <sup>a</sup> (Å)

Mg	-0.21	2.51	-0.16	2.21
O	-0.21	2.80	-0.20	2.51
Hollow	-0.21	2.83	-0.23	2.68

<sup>a</sup>This corresponds to the distance between the bottom F atom in SF<sub>6</sub> and the closest surface atom on the MgO surface.

### 3.2 SF<sub>6</sub> adsorption over O-defective MgO (001) and (111) surfaces

Deficient MgO surfaces have been proven to show a better surface property than perfect surfaces for the adsorption and activation of gas molecules and doped atoms [28, 29]. In this study, the adsorption processes of SF<sub>6</sub> over O-defective MgO (001) and (111) surfaces are calculated. The  $E_{ad}$ , the adsorption distance and optimized configurations are summarized in Table 2, Fig.3 and Fig.4.

In Fig.3, SF<sub>6</sub> undergoes a chemical adsorption over the O-defective MgO (001) surface and the O<sub>v</sub> site is the most stable site for SF<sub>6</sub> adsorption, corresponding to the highest  $E_{ad}$  of -6.66 eV. At this site, the SF<sub>6</sub> molecule decomposes to SF<sub>5</sub>\* (\*means the species is adsorbed) and F\*, where the F\* atom fills the O vacancy, as shown in Fig.3(b). Similarly, at the bridge site, the SF<sub>6</sub> molecule decomposes to SF<sub>5</sub>\* and F\*, with  $E_{ad}$  equal to -6.54 eV. However, at the Mg site, there is no decomposition of SF<sub>6</sub>, but the bottom F in SF<sub>6</sub> binds with the surface Mg, with  $E_{ad}$  of -6.01 eV.

Table 2 Adsorption energy and distance of SF<sub>6</sub> over MgO (001) and MgO (111) surfaces with O vacancy

Adsorption site	MgO (001)		MgO (111)	
	$E_{ad}$ (eV)	Adsorption distance <sup>a</sup> (Å)	$E_{ad}$ (eV)	Adsorption distance <sup>a</sup> (Å)

Mg	-6.01	1.61	-0.22	2.74
O <sub>v</sub>	-6.66	—	-0.58	—
Bridge	-6.54	—	—	—
Neighbor-O	—	—	-0.21	2.75

<sup>a</sup>This corresponds to the distance between the bottom F atom in SF<sub>6</sub> and the closest surface atom on the MgO surface.

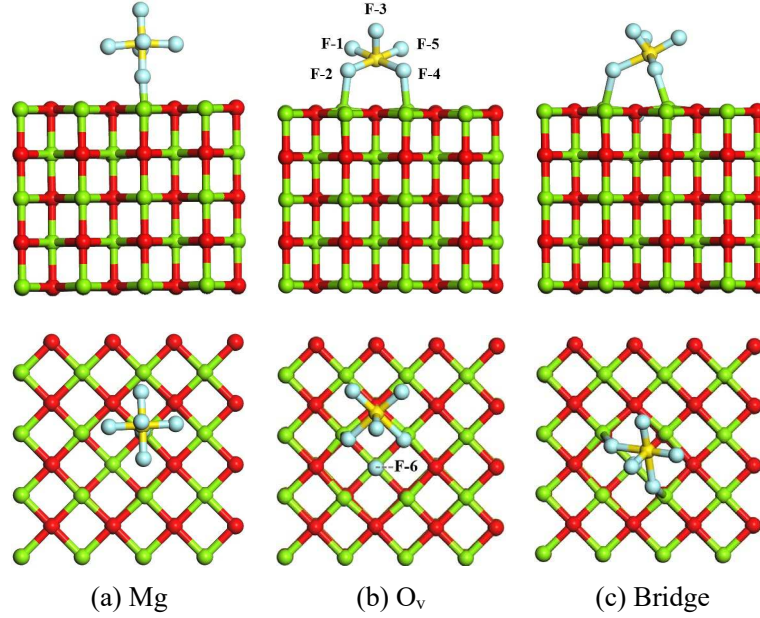

Fig. 3 Adsorption configurations of SF<sub>6</sub> over the MgO (001) surface with O vacancy, in side view (upper panels) and top view (lower panels). Green, red, yellow and blue balls are Mg, O, S and F atoms, respectively.

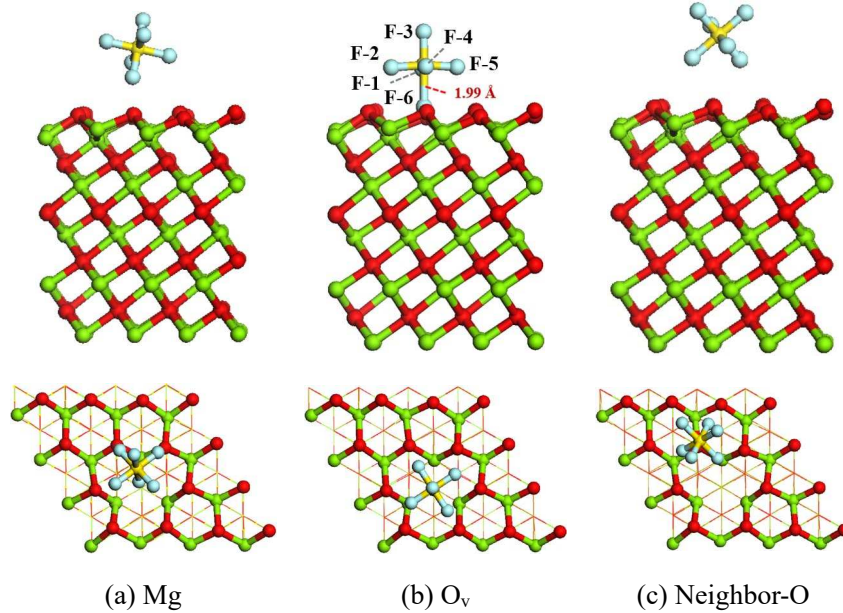

Fig. 4 Adsorption configurations of SF<sub>6</sub> over the MgO (111) surface with O vacancy, in side view (upper panels) and top view (lower panels). Green, red, yellow and blue balls are Mg, O, S and F atoms, respectively.

By contrast, over the O-defective MgO (111) surface,  $E_{ad}$  is much lower. The O vacancy is also

the most stable site for SF<sub>6</sub> adsorption, corresponding to  $E_{ad}$  of -0.58 eV. Unlike the self-decomposition of SF<sub>6</sub> over the MgO (001) surface, the adsorption of SF<sub>6</sub> at the O<sub>v</sub> site on the MgO (111) surface shows an elongation of the bottom S-F bond, from 1.61 Å to 1.99 Å (Fig.4(b)). On the other hand, in Fig.4 (a) and (c), the SF<sub>6</sub> molecule undergoes physical adsorption at both the Mg and neighboring O sites, corresponding to  $E_{ad}$  of -0.22 eV and -0.21 eV, respectively.

Table 3 Bader charge distributions of SF<sub>6</sub> in the gas phase, at the Mg site over the perfect MgO (001) surface, at the hollow site over the perfect MgO (111) and at the O<sub>v</sub> site over the O-defective MgO (001) and (111) surfaces. (Unit: eV)

Atom	Gas phase	Mg site over the perfect MgO (001)	O <sub>v</sub> site over the defective MgO (001)	Hollow site over the perfect MgO (111)	O <sub>v</sub> site over the defective MgO (111)

F-6	8.00	8.04	7.96	7.96	7.74
Sum <sup>a</sup>	0	0.06	1.95	-0.02	0.03

<sup>a</sup>The total charge here is the value after subtracting the number of electrons in the valence layer of each atom of S and F (6 for S and 7 for F), which shows the overall charge change of the SF<sub>6</sub> molecule itself after the chemical reaction. Positive values indicate the gain of electrons. F atoms are labeled in Fig.1, Fig.2, Fig.3, and Fig.4.

In order to better understanding the interaction between SF<sub>6</sub> and the O-defective MgO surfaces, we calculated the Bader charge distributions and the partial charge distributions for the most stable adsorption configurations of the MgO (001) and (111) systems, as shown in Table 3 and Fig.5. For comparison, the Bader charges of two adsorption cases over the perfect MgO surfaces, as well as the gas-phase SF<sub>6</sub> molecule are calculated and summarized in Table 3 as well. From Table 3 we can see that SF<sub>6</sub> gains 1.95 |e| after its adsorption over the O-defective MgO (001) surface. In the SF<sub>6</sub> molecule, the S atom gains 2.52 |e|, while the F-2 and F-4 in Fig.3(b) lose 0.32 |e| each, which are two F atoms bonding with the surface Mg. This indicates that a strong electron transfer occurs during the adsorption, where SF<sub>6</sub> and surface MgO atoms act as the electron acceptor and donor, respectively, leading to a valence changing of the S and F atoms in SF<sub>6</sub>. By comparison, the total charge transfer processes are very limited in other three adsorption cases, which are less than 0.1 |e|. However, from Table.3 and Fig.5(b) we can see that the F-6 (bottom F in SF<sub>6</sub>) in the MgO (111) system loses 0.26 |e| after the SF<sub>6</sub> adsorption, which weakens the S-F bond and leads to S-F bond elongation. In general, the O-defective MgO (001) surface shows a significant surface property for SF<sub>6</sub> adsorption and activation, allowing SF<sub>6</sub> to decompose into SF<sub>5</sub>\* and F\* over the surface during the adsorption. The adsorption of SF<sub>6</sub> over the O-defective MgO (111) surface is much weaker, but an elongation of the bottom S-F bond occurs, corresponding to a weaker activation of SF<sub>6</sub>. This is in contract to the behavior at the perfect MgO surfaces, where the SF<sub>6</sub> molecule hardly interacts with the surface atoms and only physical adsorption happens.

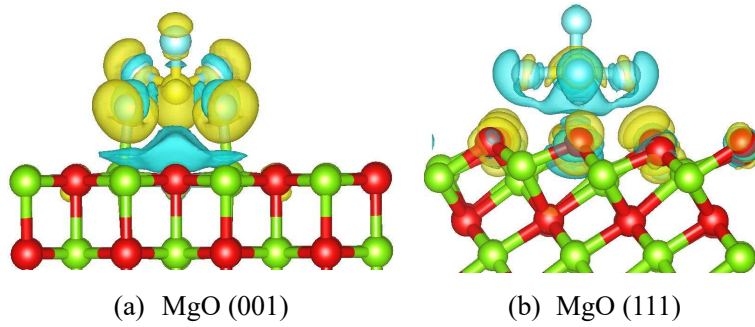

Fig. 5 Differential charge distribution of SF<sub>6</sub> at the O<sub>v</sub> site on the MgO(001) and (111) surfaces. The yellow region indicates an increase in charge density and the cyan region indicates a decrease.

### 3.3 SF<sub>6</sub> adsorption on the step-shape MgO (001) surface

The step site of the MgO surface could also be an active site for SF<sub>6</sub> adsorption [22]. As shown in Fig.6, the SF<sub>6</sub> molecule shows a deformation after adsorbing at the step site over the MgO (001) surface. The bond angle of F(2)-S-F(6) changes from 90° to 83.15° and the S-F(2) bond length increases from 1.61 Å to 1.99 Å. There is no obvious bonding process between SF<sub>6</sub> and surface atoms and the  $E_{ad}$  is -0.38 eV, which corresponds to physisorption.

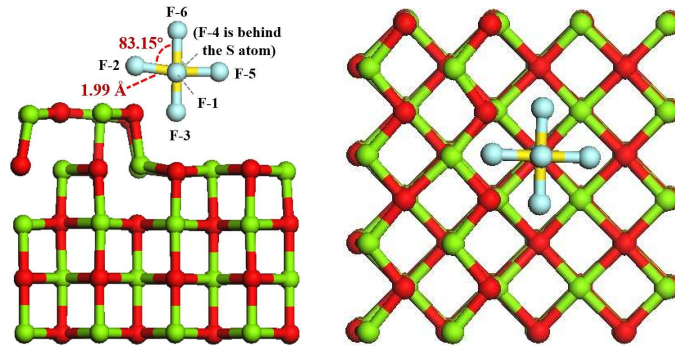

Fig. 6 Adsorption configurations of SF<sub>6</sub> over the step-shape MgO (001) surface, in side view (left) and top view (right). Green, red, yellow and blue balls are Mg, O, S and F atoms, respectively:  $E_{ad}$  = -0.38 eV.

Table 4 Bader charge distribution of SF<sub>6</sub> over the step-shape MgO (001) surface. (Unit: eV)

Atom*	Gas phase	Step site
S	0.00	0.00
F-1	8.01	7.96
F-2	7.99	7.99
F-3	7.99	8.14
F-4	8.01	8.03
F-5	8.00	7.97
F-6	8.00	8.04
Sum	0	0.13

\*Positive values indicate the gain of electrons. F atoms are labeled in Fig.6.

The Bader charge distribution is shown in Table 4. The SF<sub>6</sub> molecule gains 0.13 |e| at the step site and the charge transfer mainly happens between SF<sub>6</sub> and the step O atoms, which is also proved by the charge density difference in Fig.7. The projected density of state (PDOS) is analyzed to further study the orbital interactions between the SF<sub>6</sub> molecule and the step O atoms, as shown in Fig.8. The PDOS results show that there is a small overlap between the F atoms and the step O atoms at

about -1 eV, which may correspond to a very weak orbital hybridization. Overall, SF<sub>6</sub> mainly undergoes physisorption at the step site over the MgO (001) surface, with a weak charge transfer process. The step-shape MgO (001) weakly activates SF<sub>6</sub>, leading to a limited elongation of the S-F bond and a change in S-F bond angles.

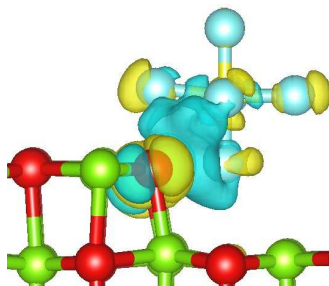

Fig.7 Differential charge distribution of SF<sub>6</sub> over the step-shape MgO (001) surface. The yellow region indicates an increase in charge density and the cyan region indicates a decrease.

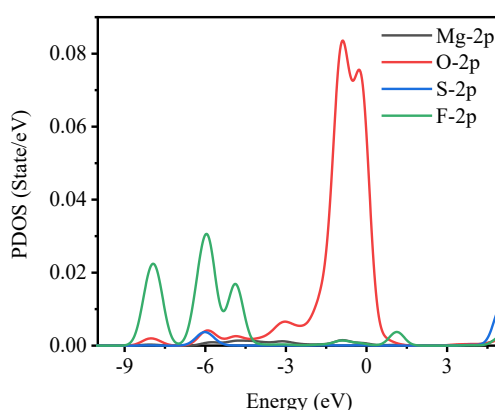

Fig. 8 PDOS for SF<sub>6</sub> adsorption over step-shape MgO (001) surface

### 3.4 SF<sub>6</sub> adsorption over H-covered MgO (111) surfaces

As previously mentioned, the terminated MgO surfaces should be carefully evaluated since the hydration process may occur in SF<sub>6</sub> degradation with H<sub>2</sub>O or H<sub>2</sub> addition. The hydroxylated MgO (111) surfaces has been proven to be more stable than clean (100) surfaces [30]. Therefore, in this study, we chose the hydroxylated MgO (111) surface as a typical case to represent the possible surface condition of MgO in thermal or NTP treatment and investigate its surface properties on SF<sub>6</sub> adsorption. Two hydroxylated conditions are set, namely 0.5 ML and 1.0 ML coverage of H for the MgO (111) surface, as shown in Fig. S3. The  $E_{ad}$  and adsorption configurations are summarized in Table 5, Fig.9 and Fig.10.

In Table 5, the  $E_{ad}$  of SF<sub>6</sub> in the 0.5 ML H-covered MgO (111) system is significantly lower than in the 1.0 ML system. As shown in Fig.9, at each site, SF<sub>6</sub> undergoes physisorption over the 0.5 ML surface without a surface binding process and  $E_{ad}$  is no more than 0.20 eV. By contrast, over the 1.0 ML H-covered (111) surface, SF<sub>6</sub> shows a significant deformation after the adsorption at the four typical sites. The H site is the most stable site, at which SF<sub>6</sub> decomposes to SF<sub>5</sub> and F after the adsorption, corresponding to  $E_{ad}$  of -4.22 eV. In Fig.10 (b), the detached F atom (F-5) is at the hollow site. Similarly, SF<sub>6</sub> decomposes at the hollow site and the bridge site, corresponding to  $E_{ad}$  of -4.05 eV and -4.14 eV, respectively. However, at the Mg site, there is no obvious detachment of F in SF<sub>6</sub>,

but an elongation of the bottom S-F bond from 1.61 Å to 2.07 Å is seen. The adsorption configurations in Fig.9 and Fig.10 show that the adsorption of SF<sub>6</sub> is much more stable at the 1.0 ML H-covered (111) surface.

Table 5 Adsorption energy of SF<sub>6</sub> over the O-terminated MgO (111) surface with 0.5 and 1.0 ML

H-coverage (Unit: eV)		
Adsorption site	0.5 ML	1.0 ML
H	-0.17	-4.22
O	-0.04	—
Mg	—	-3.13
hollow	-0.20	-4.05
bridge	-0.12	-4.14

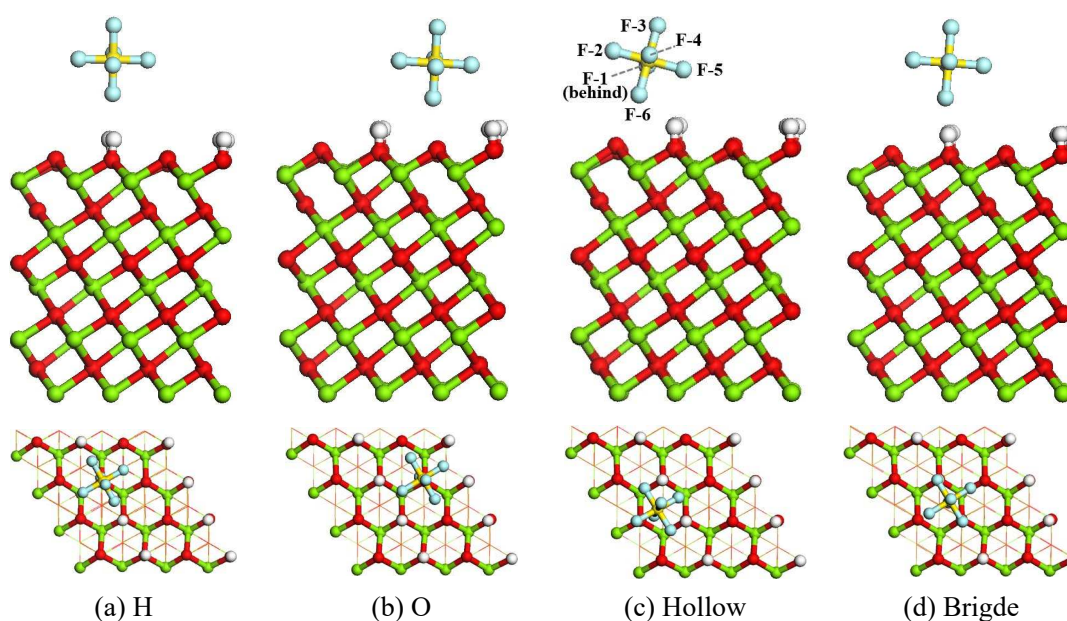

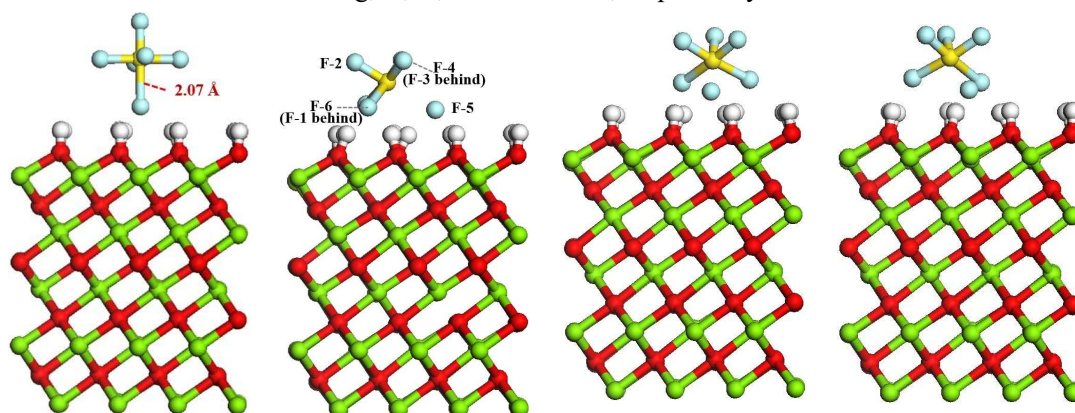

Fig. 9 Adsorption configurations of SF<sub>6</sub> over the MgO (111) surface with 0.5 ML H-coverage, in side view (upper panels) and top view (lower panels). Green, red, white, yellow and blue balls are Mg, O, H, S and F atoms, respectively.

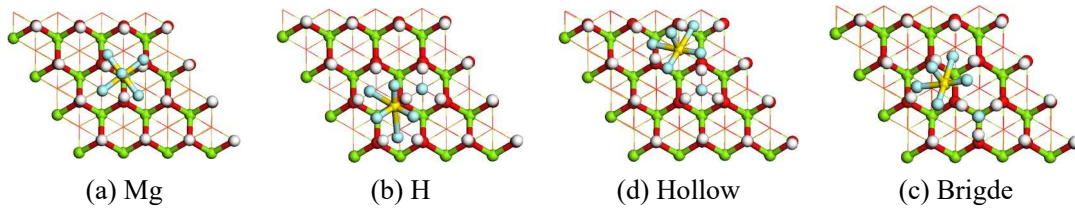

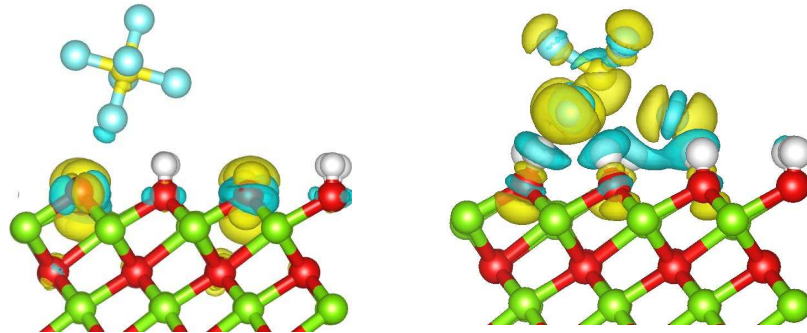

Fig. 10 Adsorption configurations of  $\text{SF}_6$  over the  $\text{MgO}$  (111) surface with 1.0 ML H-coverage, in side view (upper panels) and top view (lower panels). Green, red, yellow and blue balls are Mg, O, S and F atoms, respectively.

Bader analysis and partial charge calculation are conducted for two hydroxylated adsorption systems, as shown in Table 6 and Fig.11. It can be seen that the S atom in  $\text{SF}_6$  gains 2.34 |e| from the 1.0 ML H-covered (111) surface, while it stays unchanged at the 0.5 ML surface. The  $\text{SF}_6$  molecule gains 0.02 and 1.92 |e| from the 0.5 ML and 1.0 ML surfaces, respectively. This indicates that there is almost no charge transfer process in the 0.5 ML adsorption system but a significant transfer of electrons happens from the 1.0 ML surface to the  $\text{SF}_6$  molecule, leading to a change of the valence state of the S atom. Similar to the adsorption of  $\text{SF}_6$  over the O-defective (111) surface, the bottom three F atoms, i.e. F-1, F-5 and F-6 lose -0.32, -0.26 and -0.28 |e|, respectively, which is also proven in Fig.11 (b). Finally, from Fig.11 (a) we can see that the partial charge distribution of  $\text{SF}_6$  hardly changes over the 0.5 ML (111) surface.

Table 6 Bader charge distribution of  $\text{SF}_6$  on the 0.5 ML and the 1.0 ML H-coverage  $\text{MgO}$  (111) surface. (Unit: eV)

Atom*	Gas phase	0.5 ML Hollow site	1.0 ML H site
S	0.00	0.00	2.34
F-1	8.01	8.01	7.68
F-2	7.99	7.98	8.07
F-3	7.99	8.01	8.07
F-4	8.01	8.00	8.00
F-5	8.00	7.99	7.74
F-6	8.00	8.03	7.72
Sum	0	0.02	1.92

\*Positive values indicate the gain of electrons. F atoms are labeled in Fig.9 and Fig.10.

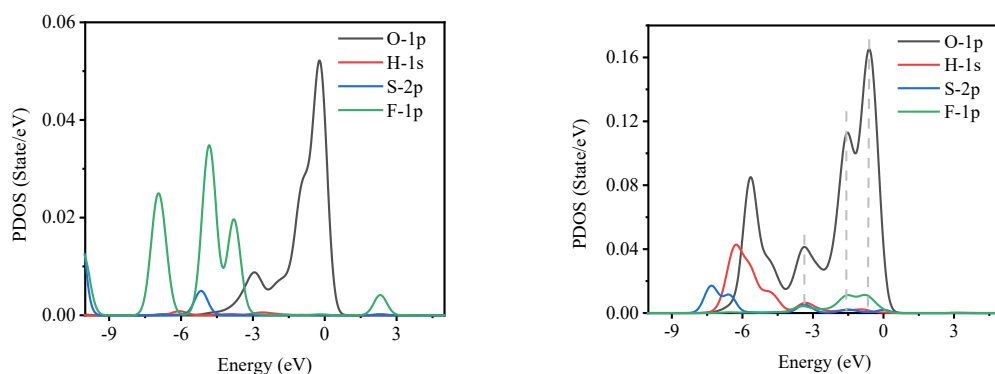

(a) Hollow site with 0.5 ML H-coverage (b) H site with 1.0 ML H-coverage

Fig.11 Differential charge distribution of  $\text{SF}_6$  at the H-covered  $\text{MgO}$  (111) surfaces. The yellow region indicates an increase in charge density and the cyan region indicates a decrease.

In order to further analyze the bonding properties of the  $\text{SF}_6$  molecule and the surface atoms, PDOS analysis is carried out for two adsorption systems, as shown in Fig.12. The PDOS results of O correspond to the surface O atoms. In Fig.12 (a) of the 0.5 ML system, there is no obvious overlap

between the orbitals of the surface atoms and SF<sub>6</sub>. However, in Fig.12 (b) of the 1.0 ML system, the F-1p overlaps with O-1p at around -1.7 eV and -0.8 eV. The S-2p and F-1p overlap with O-1p and H-1s at around -3.3 eV. This corresponds to the orbital hybridization of SF<sub>6</sub> and the surface atoms, which indicates that the detached and elongated F atoms from SF<sub>6</sub> show a chemical bonding process with the surface atoms, accompanied with a charge transfer from the surface slab to the gas molecule. In general, the 1.0 ML H-covered (111) surface shows significant surface properties for SF<sub>6</sub> adsorption and activation, which can promote the decomposition of SF<sub>6</sub> to stable adsorbates on its surface. However, over the 0.5 ML surface, only physisorption of SF<sub>6</sub> occurs.

Overall, the adsorption performance of SF<sub>6</sub> over the MgO surface is largely determined by the surface properties. The crystal type, surface defect, crystal surface shape (step site) and the surface hydroxylation are analyzed to be potential factors in affecting SF<sub>6</sub> adsorption and activation. Among them, O vacancies and surface hydroxylation of O-terminated (111) surface can both lead to the initial bond-breaking of SF<sub>6</sub> and the chemical adsorption of its decompositions, which could promote the degradation of SF<sub>6</sub>. It should be noted that in a plasma-catalysis system, the intensive discharges generated at the gas-solid (catalyst) interface can significantly change the surface structure of the catalyst, leading to the formation of surface vacancies and the pre-adsorption of plasma-generated species [10, 11]. Therefore, when packing the MgO into a plasma system for SF<sub>6</sub> degradation, the surface O vacancies and surface hydroxylation are likely to be formed by the plasma discharge, especially with the addition of H<sub>2</sub>O or H<sub>2</sub> gas. In this case, the adsorption and activation of SF<sub>6</sub> could be promoted over the MgO packing surface to obtain a better degradation performance. To fully understand the complete picture of SF<sub>6</sub> degradation in a MgO packed system, in-situ characterization of the plasma-assisted abatement of SF<sub>6</sub> can be considered in the future, and more detailed elementary reactions could be calculated when advanced product information is known.

## 4 Conclusion

In this study, the interaction mechanism between SF<sub>6</sub> and MgO surfaces are investigated via DFT calculations. Our results show that the crystal surface type and the surface structures are of great importance in determining the surface properties on SF<sub>6</sub> adsorption and activation. Over perfect MgO (001) and (111) surfaces, SF<sub>6</sub> only undergoes physisorption without bonding. By contrast, SF<sub>6</sub> undergoes chemisorption over O-defective MgO (001) surface, with the highest  $E_{ad}$  to be -6.66 eV, and SF<sub>6</sub> decomposes to SF<sub>5</sub>\* and F\* after adsorption. Besides, SF<sub>6</sub> undergoes adsorption at the O<sub>v</sub>

site over the (111) surface with  $E_{ad}$  to be -0.58 eV, accompanied with an elongation of the bottom S-F bond from 1.61 Å to 1.99 Å. Bader analysis shows that 1.95 |e| electrons are transferred from the O-defective (001) surface to SF<sub>6</sub>, leading to a change of valence state of the S atom in SF<sub>6</sub> and a weakening of the S-F bonds. In the O-defective (111) system, the total charge transfer is very limited, but the bottom F atom loses 0.26 |e|, which is attributed to the S-F bond elongation.

Besides, over the step-shape (001) surface, SF<sub>6</sub> shows physisorption at the stepsite with  $E_{ad}$  to be -0.38 eV. It is slightly activated as the S-F bond angles are changed and the bond lengths are elongated. A weak charge transfer process accompanied by a weak hybridization process occurs during the adsorption.

Moreover, as hydroxylated MgO (111) surface we considered two examples, i.e., a 0.5 ML and 1.0 ML H-covered O-terminated (111) surface. The results show that SF<sub>6</sub> can undergo chemisorption on the 1.0 ML H-covered (111) surface, but physisorption on the 0.5 ML surface. On the 1.0 ML H-covered surface, the H site is the most stable site, corresponding to the highest  $E_{ad}$  of -4.22 eV, at which 1.92 |e| is transferred from the MgO surface to SF<sub>6</sub> and a significant orbital interaction occurs between SF<sub>6</sub> and the surface atoms. By contrast, there is almost no charge transfer or orbital hybridization process in the 0.5 ML H-covered system.

Overall, our results prove that the MgO surface shows potential for SF<sub>6</sub> adsorption and activation when the surface is O defective or is hydroxylated. At these conditions, SF<sub>6</sub> can undergo self-decomposition during the adsorption, accompanied with significant charge transfer and surface bonding. Therefore, when using a packed bed DBD with MgO packing in NTP-based degradation of SF<sub>6</sub>, and the plasma affects the MgO surface, the latter can obtain catalytic properties for SF<sub>6</sub> degradation. Hence, our results can be useful to obtain more insight in the activation and initial degradation mechanisms of SF<sub>6</sub> in plasma-catalytic treatment with MgO packing.

## ACKNOWLEDGMENT

This work is funded by National Natural Science Foundation of China (Grant. 52207155). The computational resources and services used in this work were provided by the HPC core facility CalcUA of the Universiteit Antwerpen, and VSC (Flemish Supercomputer Center), funded by the Research Foundation - Flanders (FWO) and the Flemish Government.
